#### Abstract

NameTDB The Oronym Tree: A Visual Representation of the Intelligibility of Song Lyrics and other scripted text

#### Jennifer "Jenee" Gayle Hughes

In this project, we developed a visualization of the ambiguity of written prose. Given a textual phrase, our program determines all oronyms for that phrase, or possible ways that that phrase is likely to be misheard. It then creates an oronym parse-tree visualization, with each branch fork indicating that a phonetic sequence can be interpreted in more than one way. Each branch segment represents an orthographic word, and the branch radius is scaled to the word's frequency of use in everyday language.

Given any valid English phrase, our system will first generate all possible correct phonetic sequences for a General American accent. Then, it parses through these phonetic transcriptions depth-first, looking for valid orthographic words for each subsequent phonetic subsequence, generating full and partial phrases from these words. While it is doing so, a tree branch is generated on screen for each possible orthographic divergence. In the event that a branchs phonetic tail is not orthographically interpretable, we visually dead-end the branch by drawing a red sphere. In the event that the entire phonetic sequence can be parsed into a valid orthographic phrase, we indicate this successfully-found oronym with a green sphere.

This visual representation allows users to see how many ways a phrase can be interpreted, and most novely, where dead-end interpretations of the phrase's phonetic sequence exist. A particularly strong orthographic partial phrase before a phonetic dead-end can mislead a listener, causing them to lose track of the words in the rest of the phrase.

Our visual representation does not take into account n-gram word-proximity, which causes the visual representation to incorrectly weight some branch paths. However, overall, it does a fairly good job of weighting the likelihood that a listener will follow an oronym branchs particular interpretation as they listen to a phrase.

In addition to implementing the visualization, we did a multi-phase user study, incorporating over 500 data points from over 157 test subjects. In it, we tested the validity of our oronym generation by having people read a oronym phrase aloud and send us the recording, and by having people transcribe pre-recorded oronyms. In the first phase, we generated oronym strings for the phrase a nice cold hour, and had over 15 people make approximately 65 recordings of the most common oronym phrases. We then compared their pronunciations to the pronunciations we were expecting, and found that in all cases, the recorded phrase's phonemics matched our expectations. In the second phase, we selected fifteen of the phase one recordings, and had over 30 different people transcribe each one. In the aggregated transcriptions, the most commonly transcribed phrases roughly corresponded with our metric for the most likely oronym interpretation of the phrase in the recording. Though we are happy with our findings, we believe that we could create even better likelihood metrics with the integration of n-grams, and would suggest this for future work.

## Chapter 1

## Preliminary Vocabulary

Before we start, there are a few uncommon terms we will use fairly often in this paper. Our paper will make very little sense if you don't know what these things are. We have briefly defined them here.

#### 1.1 Mondegreens

A mondegreen is a word or phrase resulting from a misinterpretation of a word or phrase that has been heard[9]. The word was coined by American author Sylvia Wright in her article, "The Death of Lady Mondegreen", published in a 1954 issue of Harper's Bazaar. In it, she describes the origin of the word:

When I was a child, my mother used to read aloud to me from Percy's Reliques, and one of my favorite poems began, as I remember:

Ye Highlands and ye Lowlands, Oh, where hae ye been? They hae slain the Earl O' Moray, And Lady *Mondegreen*.

The fourth line of the quote is actually "and laid him on the green" [18].

Additional commonly-cited mondegreens include [5] [14] [16]:

Gladly the Cross-Eyed Bear

Scuse me while I kiss this guy

Scuse me while I kiss the sky

There's a bathroom on the right

There's a bad moon on the rise

#### 1.2 Oronyms

Oronyms are phrases that may differ in meaning or spelling, but sound near-identical when spoken. They are similar to mondegreens, and the terms are often used interchangeably. The difference, however, lies in the context. The label "mondegreen" is used more often in regards to music lyrics, where pronunciation can be affected by the addition of music and tone to the phrase. Oronyms, on the other hand, refer to spoken words, not sung lyrics.[?]

Common oronyms include:

i scream ice cream
an ice cold hour a nice cold hour
grape ants gray pants
real eyes realize

#### 1.3 Orthography

Orthography sounds fancy, but it's quite familiar. The word 'orthographic' comes from the Latin *orthographia*, meaning *correct* writing. Orthography itself is the part of language study concerned with letters and spelling. More specifically, it's the standardized system of writing down words in a specific language, using a commonly-accepted set of letters according to accepted usage. [10]

The orthographic symbol set for a language is the commonly-accepted set of letters used to spell words in that language. In English, our orthographic symbol set is the Latin alphabet.

In this paper, when we say "orthographic phrase", we're referring to an sequence of regularly-spelled Webster's-dictionary-type words.

Example: This is a orthographic phrase."

#### 1.4 Phonetics and Phonology

To discover oronyms for a phrase, we must first to translate the root orthographic phrase to a representation that allows us to unambiguously measure pronunciation. Phonology and phonetics are branches of linguistics that deal with pronunciation.

#### 1.4.1 Phonetics

Phonetics is a branch of *descriptive* linguistics, and refers to the study of the actual, uttered sound of human speech. It deals with describing the physical phenomena of how these sounds are produced from the vocal tract, how they are transmitted once spoken, and how they are recieved by audience. The building blocks of phonetics are *phones*, which represent atomic sounds.

#### 1.4.2 Phonology (aka phonemics)

Phonology is a branch of *theoretical* linguistics, and as such, is primarily concered with the abstract grammartical characterization of sounds. It describes

the way that sounds function within a language and give meaning to words. The basis of phonological analysis is the grouping of sounds (*phones*) into distinct units within a languages. These distinct units are called *phonemes*.

These phonemes may contain different phones, depending on the accent of the speaker. For example, native speakers of General American English only generally recognize one 'L' sound phoneme. However, there are two different ways that that phoneme manifests itself: the 'l' in "male", and the 'l' in late. This difference is not noticable to a native speaker of American English, because that particular accent will parse any 'L' phone as the same 'L' phoneme.

#### 1.4.3 Phonetics Vs Phonology

As we said previously, though the terms are sometimes used interchangably, the words 'phonemic' and 'phonetic' (and their corresponding sound building blocks, 'phone' and 'phoneme') indicate a different stages of sound parsing. *Phonemes* are idealized sounds; *phones* are the actual sounds that come out of a person's mouth. Figures 1.1a and 1.1b provide a final, illustrative metaphor of the difference.

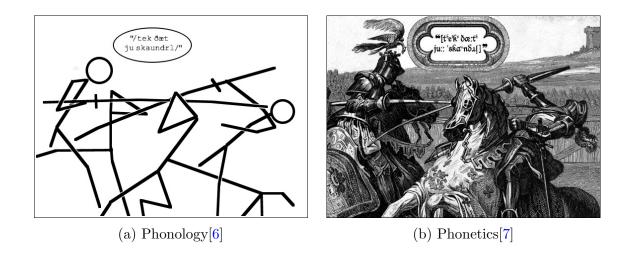

Figure 1.1: The difference between phonetics and phonology

#### 1.5 Phonemic/Phonetic Alphabets

As we stated in section 1.4.1, phonemes are the atomic building blocks of words. Think of phonemes as an alphabet where every meaningful sound has its own letter. The way that we interact with phonemes in a concrete way is by using phonetic alphabets and phonetic dictionaries.

#### doc•tor | 'däktər |

nour

1 a qualified practitioner of medicine; a physi

- a qualified dentist or veterinary surgeon.
- [ with modifier ] informal a person who give improvements: the script doctor rewrote the original information in the script doctor rewrote in the sc
- 2 ( Doctor )a person who holds a doctorate:

Figure 1.2: The characters to the right of the large bold word "doctor" are IPA symbols.

The most common phonetic alphabet is the IPA (Internation Phonetic Alphabet). It contains representations of every sound in every known language globally, and allows for cross-cultural pronunciation guidelines. As shown in figure 1.2, IPA representations of ortho-

graphic words are found in traditional dictionaries to aid pronunciation.

#### 1.5.1 **SAMPA**

SAMPA (Speech Assessment Methods Phonetic Alphabet) is a computer-readable phonetic alphabet, based upon the symbols found in the more-standard-but-not-easily-computer-readable IPA (International Phonetic Alphabet). It that uses "letters" consisting of 1-2 ASCII characters to represent each phoneme. The ASCII sequences for the SAMPA letter are designed so that any SAMPA sequence deterministically parsible.

We chose to use SAMPA instead of IPA because its ASCII-compliance makes it easy to integrate into other systems.

See 8 for a full table of each SAMPA phoneme, its description, and its subparts.

For some brief context, the SAMPA spelling of the name 'Jenee Hughes' is  $dZEni\ hjuz$ . 'Dr Zoe Wood' becomes  $dAkt@'r\ zoui\ wUd$ . 'Dr John Clements' becomes  $dAkt@'r\ dZAn\ klEm@nts$ . 'Dr Franz Kurfess' becomes  $dAk@'r\ fr\{nz\ k3'rfEs$ .

## Chapter 2

## Introduction

Human brains are built to come to single conclusions about things that have more than one interpretation. The way that you come to this end conclusion is dependent upon your experiences, cutural immersion, and language familiarity [17]. When attempting to write English phrases that will be read aloud and heard by people with other linguistic biases than you, it's important to make your prose as deterministically understandable as possible. The first step towards this is understanding and identifying how many ways a particular textual phrase be misheard, and why.

#### 2.1 You and me...and Leslie?

In the song "Groovin' (on a Sunday Afternoon)", by the Young Rascals, there's a part in the bridge that many people hear as "Life would be ecstasy, you an' me an' Leslie". In fact, the line is "Life would be ecstasy, you and me endlessly". The confusion lies with the last three syllables of the phrase. The pronunciation of each version, if spoken normally, is as follows:

Orthographic:	and Les- lie	end- less- ly
SAMPA:	@nd "lEs li	"End l@s li

In the song, the singer is doing what many singers are taught to do, to make it easier to sustain the singing of words that end with difficult-to-sing consonants: the unsingable consonant is displaced onto the front of the next word. In this case, the consonant "d" is not singable, so he displaces it onto the next syllable, when he can: "and ME" becomes "an dME", and "end LESS" becomes "en dLESS".

Basically, singers are \*born\* to ignore syllable boundries. So, our singer can effectively think of the sung phrase as:

#### YOU an dME en dLESS lee

This does not cause confusion for listeners, because they are used to hearing it. This does mean, however, that lyric placement does not provide an accurate barometer to a listener of where a word actually ends.

In addition, the singer is singing fudging his vowels, like singers are taught to do, so "and" and "end" sound almost indistinguishable. So, really, what listeners are hearing is this:

#### YOU en dME en dLESS lee

Now, the listener's brain has to take this syllabic gobbledy-gook, and parse it into something useful. They've currently got this mess to deal with (represented in SAMPA syllables):

#### ju En dmi En dl@s li

They parse the first part just fine, because the emphases match:

#### you and me En dl@s li

But no one says endLESSly. People say ENDlessly. So, the listeners don't recognize it. They have to work with what they have. They already turned one "En d" into an "and", so they do it again:

#### you and me and l@s li

Now, they're just left with LESS lee. And that fits Leslie, a proper noun that fits in context and in emphasis placement. So, the final heard lyric is:

#### you and me and Les- lie

The misunderstanding can be traced back to improper emphasis placement. The songwriter probably didn't even think of that, and now he's stuck: a one-hit-wonder with a misunderstood song. We bet that in interview after interview, someone asks him who Leslie is. It's probably very frustrating — especially since he could have just moved the word an eight note later, and it would have been understood perfectly.

That's the sort of situation this program is going to help avoid.

#### 2.2 Why it breaks down

There are two points at which the author's intendeded phrasing can be muddled: First, when the author's orthographic text becomes an orator's spoken (phonetic) interpretation, and second, when the orator's phonetic interpretation is translated phonetically by an audience into a perceived orthographic phrase. Both of these interpretations must be made successfully in order for the author's intended meaning to be conveyed.

The phrase "iced ink" undisputedly succeeds in the first translation, but fails on the second. Iced ink can only be pronouced one way, but it can be heard multiple ways—the most notable of which is "I stink", not "iced ink".

The phrase "a nice cold hour" can fail on both parts. First, the orator could have accidentally-capitalized the word Nice in their head, and made it sound like Nice, the city in Rome. An audience would likely hear this as "niece", and would be confused, at best. Even if the orator pronouces the phrase as the author intended, they audience could hear multiple orthographic phrases in the same phonetic sequence: "a nice cold hour", "an ice cold hour", or even "a nigh scold our".

A third, more rare and nefarious type of audience misunderstanding can be caused by parse-tree misdirection, where an audience member is absolutely sure they're hearing one phrase, only to get lost halfway through the lyric. to be continued, but this will tie in to the dead ends spheres on the ends of my branches

# Chapter 3

## Background

I think I decimated this section when I wrote the Preliminary Vocab section.

Is there something else that should go here?

## Chapter 4

## Implementation

This program has three major functional parts: a custom phonetic dictionary, a command-line or onym generator, and a OpenGL or onym-parse-tree visualization generator.

#### 4.1 Customized Phonetic Dictionary

In order to discover oronyms for each phrase, we first needed to determine how each phrase is pronounced. Pronunciation can vary depending on the speakers accent, so it was important for us to (1) chose an accent that we could easily replicate and (2) find a dictionary that supported that accent.

We decided to utilize a General American accent, due to its ubiquity in media and news sources. The General American accent, also known as the "Standard American English" dialect, is not spoken by the majority of people in America, but is used as a sort of "average accent". It most closely resembles the Midwestern accent using in the area in Figure 4.1 and more commonly recognized as "the

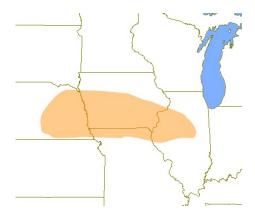

Figure 4.1: This is the geographic area whose accent most closely resembles the General American Accent [4]

newscaster accent". Newscasters learn this accent for national TV, because it is the "least-accented" of the American accents.

#### 4.1.1 Dictionary Options

We considered using three different phonetic dictionaries: the CMU dictionary, LC-STAR dictionary and UNISYN dictionary[8] [1] [12]. We started out by looking at the LC-STAR dictionary, but quickly decided that it wasnt going to be as useful to us, because the LC-Star project is relatively focused on Speech-to-Speech or Text-to-Speech tech. Also, the website had not been maintained since 2006.

We then tried the CMU dictionary, which, for a while, seemed like it was going to work. It had a very simple way of encoding words: first the word, then the identifier number in parens (if needed), then a space, then a one-to-two char code for each sound in the word, with the numbers 0, 1, 2 appended to indicate emphasis (if needed), separated by spaces. An example of a CMU dictionary

#### ABBREVIATE AHO B R IY1 V IYO EY2 T

Figure 4.2: Here is the CMU dictionary entry for the word "abbreviate"

entry can be seen in Figure 4.2.

The problem that arose with this format, was that there was no explicit definition of where to hyphenate the word when splitting it up. This causes problems if I want to use the word in lyrics, where each note has is own syllable underneath it, and each syllable might have many different sounds. The benefits of the CMU dictionary over some other dictionaries were that (1) it was actively maintained, (2) it included proper nouns, which are often found in lyrics, but not in dictionaries, and (3) it was ridiculously easy to read.

The downsides were that (1) it included no part of speech data or hyphenation data, and (2) it used non-standard symbols for its phonetic alphabet. With the downsides and benefits in mind, the CMU dictionary could not be used in isolation, especially if we someday want to attempt generation of original lyrics (which part of speech data would be vital for).

The UNISYN dictionary is used primarily to phonetically translate words into multiple accents. It has its own formated dictionary, with a bunch of wildcards in it. They also provide some semi-functioning perl scripts that allow you to specify a dialect youd like to use (For example, a Californian would say cooking differently than someone from the Deep South, and both would say it differently than someone from London. However, they are all speaking English. The UNISYN dictionary facilitates this translation).

It had all the information we needed, and then some. However, it was caseinsensitve, meaning that it didn't make it easy to differenciate pronunciations for some words. For example, the word "nice" is pronounced differently from the city "Nice", but they were both stored as "nice" in the orthography of UNISYN. The CMU dictionary did keep track of capitalization. The obvious conclusion, then, was to grab the capitalizations from the CMU dictionary and put them in the UNISYN dictionary, aligning them by pronunciation and part of speech.

However, we ran into a setback, mentioned in the very first article we found references to both dictionaries in: the dictionaries were inconsistent[15]. They didn't always put stresses in the same place, nor did they always have the same pronunciation. Because of this, it was difficult to match wordsespecially words that were homographic heteronyms (same writing, different sounds, like "Do you know what a buck *does* to *does*?"). Because of this, we decided to use the UNISYN dictionary exclusively.

#### 4.1.2 Formatting the dictionary

We used the UNISYN dictionary, using General American SAMPA output, as the base for our phonetic dictionary.

First, we downloaded the dictionary and related files from the UNISYN website.

Once we'd extracted them, we attempted to run the provided perl scripts to turn the UNISYN meta-phonetic symbols into SAMPA phonetic symbols, using the procedure specified in Section 6.1 of the UNISYN Documentation, and the towncode gam (which indicated that we want pronunciations using the G-eneral AM-erican accent)[13].

There were a few errors in translation we fixed manually:

#### Example:

```
transfer : 2 : VB/VBP : tr\{ns"f3"r : tr\{nsf3"r : \{trans==fer\}\} : 7184
```

Figure 4.3: Here is an example an entry in our custom phonetic dictionary, using the word "transfer"

- The translation script had erroneously substituted the character d instead
  of the digit 4, which primarily affected the unique identifiers to disambiguate words and the word-frequency counts. We did a simple search-andreplace to fix this, excluding the orthographic, extended orthographic, and
  SAMPA spellings.
- The translation script had erroneously substituted the digit 5 instead of the character l (lower case L). This interfered with the phonetic/sampa spellings of the words. Fortunately, 5 is not a valid SAMPA phoneme or orthographic letter value, so we removed all instances of it from the ortho, SAMPAspelling, and extendedOrtho columns
- The translation script had erroneously substituted the character sequence r instead of r. We were able to fix this by simply removing all haracters from our output.

#### 4.1.3 Custom dictionary fields

Here is the format for the fields in an entry in our custom phonetic dictionary, after we were done with fixing the UNISYN output:

<ortho> is the regular spelling of the word

<uniqueID> is a number (and optional string) used to differentiate homographs.

<partOfSpeech> is used to identify the specific part of speech

**SAMPAspelling>** is the breakdown of the word, phonetically. It uses the SAMPA alphabet, and separators to show where breaks in the word are, and how theyre emphasized. If a separator is '\$', the following phones (until the next separator) are not emphasized. If it's '%', then they are the secondary emphasis. If it's '"', then they are the primary emphasis.

 $\langle SAMPAnoEmph \rangle$  is the same as  $jSAMPASpelling_{\dot{c}}$ , but with all emphasis characters stripped out. We chose to add this field so that we could more-easily look up phonetic sequence matches.

<extendedOrtho> has no particular use to me, at this time. It indicates the morphological breakdown of the word, allowing for stemming analysis of words. Since we arent convering that, we never use this field.

<freq> is the frequency at which the word occurs in language, according to UNISYN. The frequency count is "taken from a composite of a number of on-line sources of word-frequency. It includes frequencies from the British National Corpus and Maptask, and frequencies derived from Time articles and online texts such as Gutenberg. They were weighted to give more importance to sources of spoken speech, and also to increase the numeric frequency of smaller corpuses" [13].

An example of a entry in our custom phonetic dictionary can be seen in Figure 4.3.

#### 4.1.4 Transferring the dictionary to a sqlite database

Because there are several hundred thousand entries in our phonetic dictionary, it was necessary to have a database, rather than store them all in-program in a multi-dimensional array. We decided to use a SQLite database for this purpose.

To turn the colon-delimited dictionary file into a SQLite database, we decided to use a program called the SQLite Database Browser, an open source, public domain, freeware visual tool to create, design, and edit SQLite3.x database files. We specifically used version 2.0b1 of the program, which was built with version 3.6.18 of the SQLite engine[11].

From that point on, it was just a matter of changing the ':' delimiter in our phonetic Dictionary.csv to a '|' delimiter, and letting the program convert the pipe-delimited csv into a sqlite database. After letting this process run for a day and a half, it finally spit out a sqlite database file.

#### 4.2 Oronym Generation

#### 4.2.1 Step 1

First, our program takes given an orthographic phrase to find oronyms for.

We then tokenize this phrase into its component words, using whitespaces as a delimiter.

For each word in the phrase, we query our phonetic dictionary for all possible SAMPA pronunciations.

'a', 'nice', 'cold', 'hour'

 ${}^{`}a' \rightarrow e, @, A$   ${}^{`}nice' \rightarrow naIs, nis$   ${}^{`}cold' \rightarrow kould$   ${}^{`}hour' \rightarrow aU`r$ 

Figure 4.4: In this and all subsequent diagrams, a 'string in quotes' indicates an orthographic word or phrase, and a monospaced string indicates that it is a SAMPA word or phrase.

Now that we have the pronunciation of each of the words in the form of SAMPA strings, we can list all the possible phonetic permutations of the original phrase.

e naIs kould aU`r

@ naIs kould aU`r

A naIs kould aU`r

e nis kould aU`r

@ nis kould aU`r

A nis kould aU`r

**Figure 4.5:** 

The pseudocode to do this is in ??.

#### 4.2.2 Step 2

Then, for each phonemic phrase, we want to figure out all valid orthogrpahic interpretations. For this, we have to go back to our phonetic dictionary.

The ideal way to think about searching for words in a phonetic sequence is by picturing the phoenetic sequence in a tree form. For example, if I had a phonetic tree with the entire dictionary in it, each phonetic tree node would have at least 45 child nodes: one for each phone. A node might also have "word" nodes, if the phones along the path to that node constructs a valid orthographic word:

When there are multiple orthographic interpretations at a single phonetic node, the most likely interpretation can be determined by checking the frequency of use for each word. For example, the sequence "n aI s" is much more likely to be "nice" than "gneiss". In figure 4.6, An visual representation of the process of going through an entire dictionary's phonetic tree for nodes along the paths for the SAMPA sequences 'aIs' and 'nice'.

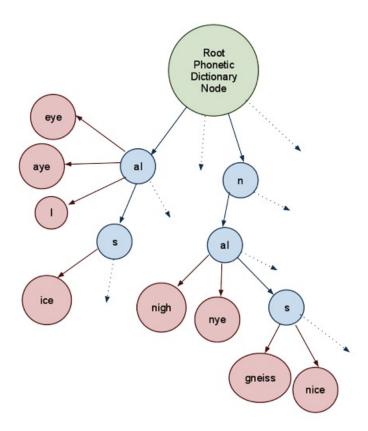

Figure 4.6:

We can use this dictionary tree method to discover valid orthographic interpretations for each phonetic sequence. Using the dictionary tree method above, we can orthographically interpret each phonetic transcription of our root orthographic phrase, as shown in figure 4.7:

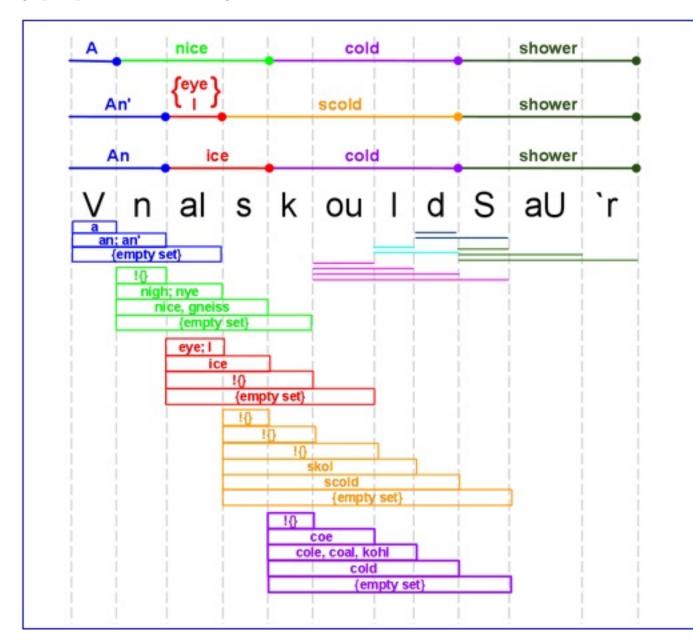

Figure 4.7:

Once we have grabbed all the orthographic interpretations for each phonetic

sequence, we combine them all into a orthographic oronym phrase list. This process may leave us with some redundant oronyms, so we de-duplicate that list.

This process gives us a list of all unique and valid oronyms for the original root phrase.

In the case of "a nice cold hour", this returns 290 oronyms.

The psuedocode for this can be found in figure ??

#### 4.2.3 Word Frequency Evaluation

Next, we want to evaluate all our oronyms based on how common each oronym's component words are. For example, "a nice cold hour" is much more likely to be heard "a gneiss cold hour", even though both are phonetically identical.

To do this, we tokenize each oronym phrase into its component words, using once again using non-newline whitespaces as a delimiter.

there is still more to be written after this point

#### 4.2.4 Text-based approach

### 4.3 Visual Representation

```
vector< vector < phone > >findAllPhoneSeqsForOrthoPhrase( string orthoPhrase) {
  vector< vector < phone > > allFullPhrasePhoneSeqs
  vector<string> orthoWords = split(orthoPhrase);
  int origNumFullPhrases = 0;

# Chapter 5

# User Study

#### 5.1 Structure

We created a multi-wave user study to examine the effectiveness of different parts of our program. I feel like I have multiple personality disorder writing in third person like this.

In the first wave, we had **NUM TO BE COUNTED** people record over 56 different phrases, to see how they pronouced them. This wave served two purposes: one, to gather recordings for the second wave, and two, to see if our phonemic transcriptions were valid.

### 5.2 User Population

We drew our test subjects from a pool of Amazon Mechanical Turk workers (hired for \$ 0.02 to \$ 0.10 per task) and, for part of phase 1, volunteers from Reddit.com [2] [3]. To avoid self-selection bias, we threw out the volunteer's data

from phase 1.

Amazon Mechanical Turk is an online crowdsourcing service where requesters

can hire workers to complete Human Intelligence Tasks, or HITs. The efficacy of

using mechanical turk for user studies has been widely studied in academia, and

specifically proven in the linguistic community?

5.3 Methodology

Get ready for figures-without-explanation bombardment. I'm getting there, I

promise.

5.3.1First Wave: Recitation

In this wave of the user study, we used a combination of **NUM TO BE** 

COUNTED Mechanical Turk workers (hired for \$ 0.10 per task) and volunteers

from Reddit.com [2] [3] to record 58 different phrases.

The recordings for "fourth rye to" were all unusable for phase two, because

people get WAY too excited when you ask them to say the word "ooh".

Second Wave: Transcription 5.3.2

## Results

PUT NGRAMS DIAGRAM HERE: http://books.google.com/ngrams/graph?content=nice+cole

#### 6.0.3 Individual Recording/Transcription Breakdowns

A recording-by-recording transcription breakdown reveals more interesting data. Each bubble charts represent the most common transcriptions for the recorded phrase listed at the top. The size of the bubble and the position along the x axis is indicative of the number of times that phrase was transcribed for this particular recording. The position along the y axis shows how often this phrase was transcribed over all the recordings.

Note that, for the purposes of clarifying these graphs, we did not chart any anomalous transcriptions—that is, transcriptions with only one occurance in this recording, or transcriptions with less than 5 percent of the recording's transcriptions with no other occurances over the entire set of recordings. Doing so did not give us useful visual data, because the bubbles stacked and obscured eachother. A full table of the transcriptions per recorded phrase can be found in the appendix

## **Global: Most Common Phrase Transcriptions**

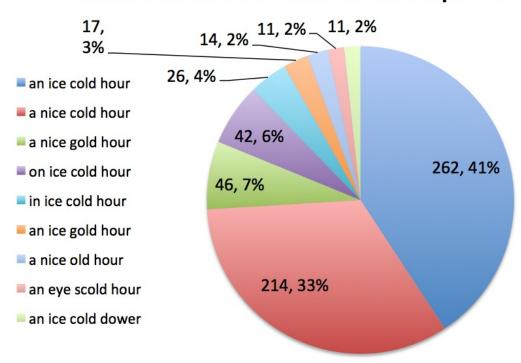

Figure 6.1: Our top two transcriptions were "a nice cold hour" and "an ice cold hour"

### **USA: Most Common Phrase Transcriptions**

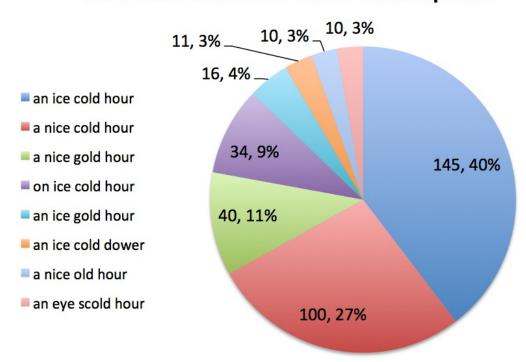

Figure 6.2: Though the breakdown is a bit different than the global transcription breakdown, you can still see the clear trend of "a nice cold hour" and "an ice cold hour" being the most common. There is a slightly larger gap between these two phrase, we hypothesize, because the American transcribers are familiar with what words normally are in proximity to others.

freq	phrase transcribed	total answers		
931028	an ice cold hour	262		
7851662	a nice cold hour	214		
7820004	a nice gold hour	46

# Chapter 7

## **Future Work**

this section not yet edited or read through for consistency. It is likely to change and grow quite drastically and without notice

### 7.1 Target Audience and Goals

This program is to be used as a compositional aid by anyone who wants to write songs and make them sound good, technically. It should allow the song writer to focus on more subjective criteria of what makes a song "good", because it will make the structural rules of lyric composition immediately apparent.

Our hope for this project is that it will be useful to burgeoning songwriters, who have the creative spark to make wonderfully poetic lyrics, but lack the "ear" to match their lyrics successfully to music. It should be particularly helpful to songwriters who place a high emphasis on understandability of lyrics (such as parody song writers, or lyricists for musical theater).

Additionally, Melody Matcher will be useful for songwriters for whom English

is a second language. While they may be a master lyricist in their native language, writing lyrics in English can be a particular challenge, since so much of lyric-writing is dependent upon knowing the cadence of the language you're writing lyrics in, and since English has no easily-discernible rules for emphasis placement in words.

### 7.2 Melody Matcher Alpha

This thesis is a part of the Melody Matcher suite. Melody Matcher is a semi-automated music composition support program. It analyzes English lyrics along with a melody, and alerts the composer of the locations in the song where the lyrics are not deterministically understandable. Basically, it's grammar- and spell-check for songs. This is significant, because very little research has been done specifically on the quantifiable measurement of English-language lyric intelligibility, other than our project.

Melody Matcher aims to replicate the human ability to identify lyrics in a song that are easily misheard. We started on this project, thinking that there would be carefully-specified research on how lyrics match melodies, mathematically. As it turned out, there was very little objective literature on the subject. Because of the lack of objective information of the subject, we had to develop our method from scratch. As we progressed through our work, we went from thinking that understandability depended only on emphasis-matching, to realizing that syllable length played a huge part as well, to realizing that there are many other musical, harmonic, and linguistic factors.

Melody Matcher analyzes the intelligibility of song lyrics by investigating several root causes:

- Lyric/Music emphasis mismatch, due to:
  - Note intervals
  - Phrase emphases
  - Word emphases
- Word "cramming", due to:
  - Syllable lengths that exceed that of note length
  - Mouth movement delta time intervals
- Word misidentification, due to:
  - Altered pronunciation of words
  - Phone similarity
    - \* Voicing (voiced vs. voiceless)
    - \* Beginning/end mouth positions
    - \* Type (Plosive, Fricative, affricate, nasal, lateral, approximant, semivowel)
  - Phone sequences with multiple syntactically-correct interpretations

The fully-implemented Melody Matcher program will eventually take into account all of these causes of unintelligibility. In this abstract, we will focus on lyric/emphasis mismatch, which has already been implemented and is fully functional in primary testing. The other sections have been implemented, but are not fully tested and/or integrated into the main program.

This is where the abstract goes. Hopefully this document will serve as an example for preparing a Cal Poly Master's thesis. It was thrown together pretty quickly. A lot more neat LaTeX features, help, and examples can be found on the web. Here is one: http://en.wikibooks.org/wiki/LaTeX

For developing LaTeX documents in the Windows environment, I use TeXnic-Center (http://www.toolscenter.org/). A simple WYSIWYG LaTeX editor (though I had problems getting it to work with this thesis format) is **LyX** (http://www.lyx.org/).

I use InkScape (http://www.inkscape.org/) to create any drawings/figures needed. It is a free vector graphics editor that is very powerful and popular. There is an example figure produced with InkScape in Figure ??. InkScape can export images in many different formats. Export your images as PDF or EPS and put into your LaTeX document. If you're creating a PDF document with pdflatex, then export as a PDF image. If you're creating PostScript then export as EPS. Rasterized images such as JPEG can also be easily included in LaTeX.

LaTeX can also produce nice equations. Did you know that  $\sum_{n=0}^{\infty} \frac{(-1)^n}{2n+1} = \frac{1}{1} - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} - \cdots = \frac{\pi}{4}$ ? A non-inline equation can be found in Figure ??. I treated my equations as figures but they can be treated specially as Equations.

An example of a table can be found in Table ??.

The bibliography section is very easy to create. When gathering references, I used the ACM digital library (http://portal.acm.org/portal.cfm) to grab the

Bibtex entries. Papers in the digital library have Bibtex entries ready to be copied and pasted into your bibliography. Create a separate file called something like "bibliography.bib" and paste in your Bibtex entries. LaTeX (and Bibtex) generate your bibliography section for you – very easy! I can cite references very easily. Here is a paper called *Dual contouring of hermite data* [?]. Here is a paper called *Surface simplification using quadric error metrics* [?]. I've also cited software located at some websites [?] [?].

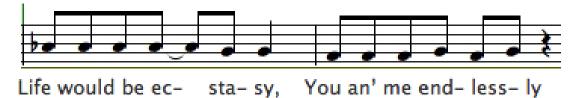

## 7.2.1 PRACTICAL EXAMPLE OF UNDERLYING THE-ORY

The structural rules of lyric placement are important, because without them, lyrics can become muddled and/or unin- telligible. For example, in the song "Groovin' (on a Sunday Afternoon)", by the Young Rascals, there's a part in the bridge that many people hear as "Life would be ecstasy, you an' me an' Leslie". In fact, the line is "Life would be ecstasy, you and me endlessly". The confusion lies with the last three syllables of the phrase. The pronunciation of each version, if spoken normally, is as follows:

Alphabetic:	and Les- lie	end- less- ly
SAMPA:	@nd "lEs li	"End l@s li

So, in the first phrase, we see that the emphasis pattern can be simplified to "dum DUM-dum", where the first syllable of "Leslie" is emphasized. The second phrase's emphasis pattern is "DUM-dum-dum", so the first syllable of "endlessly" is emphasized. When words are put to music, however, the musical emphasis overrides the textual emphasis. Sometimes, the meaning of the phrase can change, if a previously un-emphasized syllable becomes emphasized, or a

previously emphasized syllable loses its emphasis. For "Groovin", the lyrics match up to the music in the song as follows:

In this musical phrase, the emphasis always goes on the first part of a beat (for the purposes of this example, a "beat" is defined as a quarter note). In this case, the first measure is emphasized for the notes that correspond to the lyrics, "Life", "be", "ec-" (as in ec-sta-sy) and "sy" (again, as in ec-sta-sy) (This is a vast oversimplification, but it works for now). So, the lyrics would be emphasized as such:

Or, more simply:

- 1. Life would be ec-sta-sy
- 2. <u>Life</u> would <u>be</u> <u>ec</u>-sta-sy
- 3. Life would be ec-sta-sy
- 4. Life would be ec-sta-sy
- 5. <u>Life</u> would <u>be</u> <u>ec</u>-sta-<u>sy</u>

- 6. <u>Life</u> would <u>be</u> <u>ec</u>-sta-<u>sy</u>
- 7. <u>Life</u> would <u>BE</u> <u>EC</u>-sta-<u>SY</u>
- 8. <u>Life</u> would <u>BE</u> <u>EC</u>-sta-SY
- 9. <u>Life</u> would <u>BE</u> <u>EC</u>-sta-<u>SY</u>
- 10. Life Would be ec-sta-sy
- 11. Life would be ec-sta-sy
- 12. Life would be ec-sta-sy
- 13. Life WOULD be ec-STA-sy
- 14. Life would be ec-sta-sy
- 15. Life would be ec-sta-sy
- 16. Life would be ec-sta-sy
- 17. Life would be ec-sta-sy
- 18. Life would <u>be</u> <u>ec</u>-sta-sy
- 19. Life would be ec-sta-sy
- 20. Life would be ec-sta-sy
- 21. LIFE would BE EC-sta-sy
- 22. Life would be ec-sta-sy
- 23. LIFE would BE EC-sta-SY
- 24. Life would be ec-sta-sy

This musical emphasis matches the spoken emphasis of the phrase, so it is

intelligible as a lyric. (Though ecstasy's first syllable doesn't start on the first

part of beat three, it is still on the first part of beat three, and therefore still

emphasized. Alternatively, since the first part of beat two didn't have a hard

stop to it, the emphasis could have rolled over to the second part, "ec", which

does have a hard stop.)

In contrast, take the second measure: the syllables "You", "me", and "less"

are emphasized in the music. This leads to conflicting musical and spoken phras-

ing:

Musical Phrasing: You and me endlessly

Spoken Phrasing: You and me endlessly

The singer is now singing the phrase, syllable by syllable, which they think

of as syllable-note combinations:

YOU and ME end LESS lee

The singer, for his part, is doing what many singers are taught to do, to make

it easier to sustain the singing of words that end with unsingable consonants: the

unsingable consonant is displaced onto the front of the next word. In this case,

the consonant "d" is not singable, so he displaces it onto the next syllable, when

he can: "and ME" becomes "an dME", and "end LESS" becomes "en dLESS".

So, the singer can effectively think of the sung phrase as:

YOU an dME en dLESS lee

68

This doesn't cause confusion for listeners, because they're used to hearing it. This does mean, however, that lyric placement does not provide an accurate barometer to a listener of where a word actually ends.

In addition, the singer is singing fudging his vowels, like singers are taught to do, so "and" and "end" sound almost indistinguishable. So, really, what listeners are hearing is this:

#### YOU en dME en dLESS lee

Now, the listener's brain has to take this syllabic gobbledy-gook, and parse it into something useful. They've currently got this mess to deal with (represented in SAMPA syllables):

#### ju En dmi En dl@s li

They parse the first part just fine, because the emphases match:

### you and me En dl@s li

But no one says endLESSly. People say ENDlessly. So, the listeners don't recognize it. They have to work with what they have. They already turned one "En d" into an "and", so they do it again:

### you and me and l@s li

Now, they're just left with LESS lee. And that fits Leslie, a proper noun that fits in context and in emphasis placement. So, the final heard lyric is:

#### you and me and Les- lie

The misunderstanding can be traced back to improper emphasis placement. The songwriter probably didn't even think of that, and now he's stuck: a one-hit-wonder with a misunderstood song. We bet that in interview after interview, someone asks him who Leslie is. It's probably very frustrating — especially since he could have just moved the word an eight note later, and it would have been understood perfectly.

That's the sort of situation this program is going to help avoid.

LaTeX is a document markup language and document preparation system for the TeX typesetting program.

It is widely used by mathematicians, scientists, philosophers, engineers, and scholars in academia and the commercial world, and by others as a primary or intermediate format (e.g. translating DocBook and other XML-based formats to PDF) because of the quality of typesetting achievable by TeX. It offers programmable desktop publishing features and extensive facilities for automating most aspects of typesetting and desktop publishing, including numbering and cross-referencing, tables and figures, page layout and bibliographies.

LaTeX is intended to provide a high-level language to access the power of TeX. LaTeX essentially comprises a collection of TeX macros, and a program to process LaTeX documents. Since TeX's formatting commands are very low-level, it is usually much simpler for end-users to use LaTeX.

LaTeX was originally written in 1984 by Leslie Lamport at SRI International and has become the dominant method for using TeXfew people write in plain TeX anymore.

LaTeX is based on the idea that authors should be able to focus on the meaning of what they are writing, without being distracted by the visual presentation of the information. In preparing a LaTeX document, the author specifies the logical structure using familiar concepts such as chapter, section, table, figure, etc., and lets the LaTeX system worry about the presentation of these structures. It therefore encourages the separation of layout from content, while still allowing manual typesetting adjustments where needed. This is similar to the mechanism by which many word processors allow styles to be defined globally for an entire document, or the CSS mechanism used by HTML.

# Chapter 8

## Conclusion

#### This will be *significantly* expanded

Our oronyms trees effectly display all the phonetically-matched oronyms that our users came up with. In the future, we'd like to integrate ngrams, and several phoneme-swapping strategies mentioned in future work.
